# Neuroblastoma Introduction

- Tumor of sympathetic neural crest origin, often in the adrenal gland
- Occurs in young children (median age 22 months)
- Most frequent pediatric extra-cranial solid tumor: 8-10%
  - Low and intermediate risk neuroblastoma:
    - ≈ >90% EFS survival with ongoing de-escalation strategies
  - High-Risk neuroblastoma:
    - ≈ 40% EFS in spite of intensive strategies

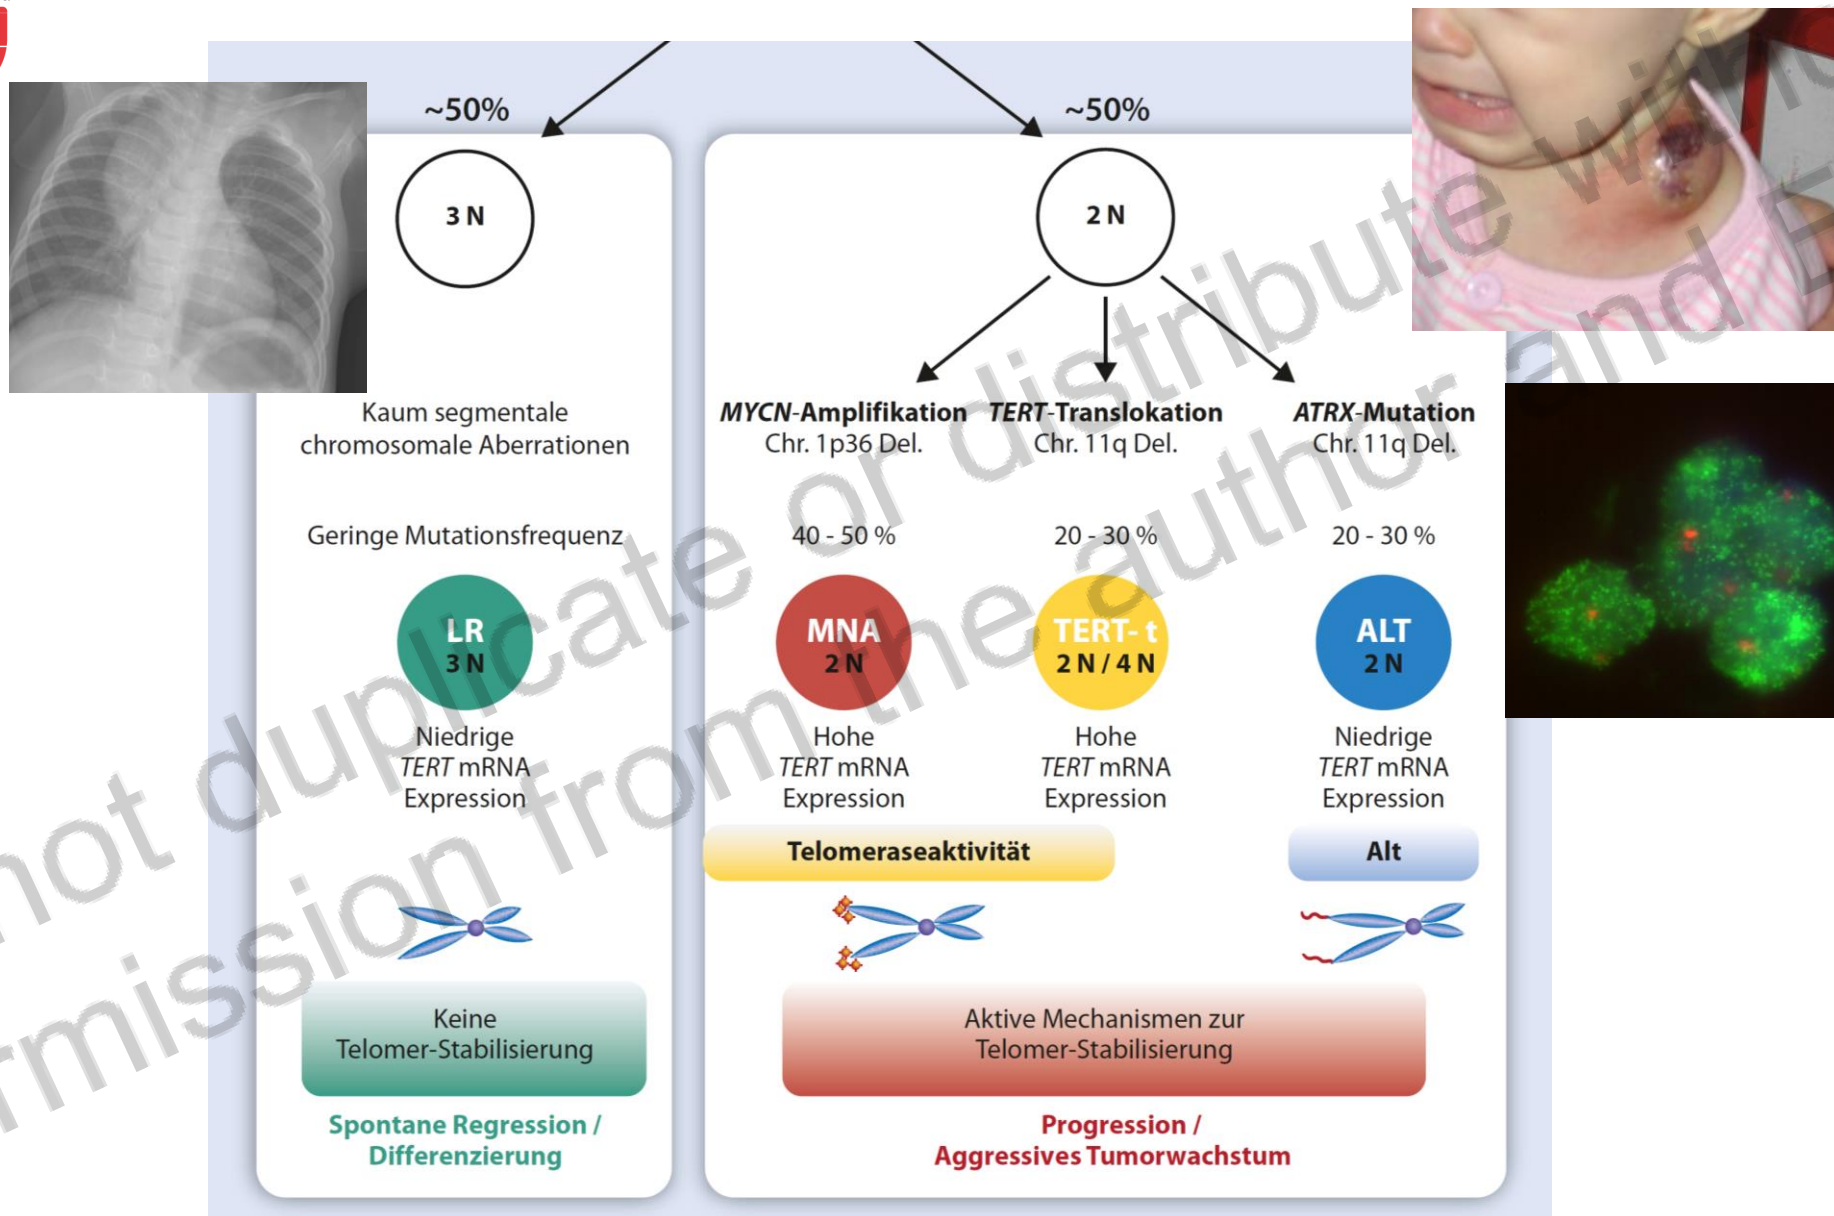

# Standard Diagnostics

- Tumor markers:  
Urin Catecholamines: HVA, VMA, Dopamin
- Serum: neuronspezifische Enolase (NSE), Ferritin, LDH
- CT/MRI (Ultrasound)
- Uptake in mIBG-Scintigraphy
- Tumor biopsy: histology & tumor genetics
- Bone Marrow (aspirates, trephines)

# Genetic Markers in Neuroblastoma

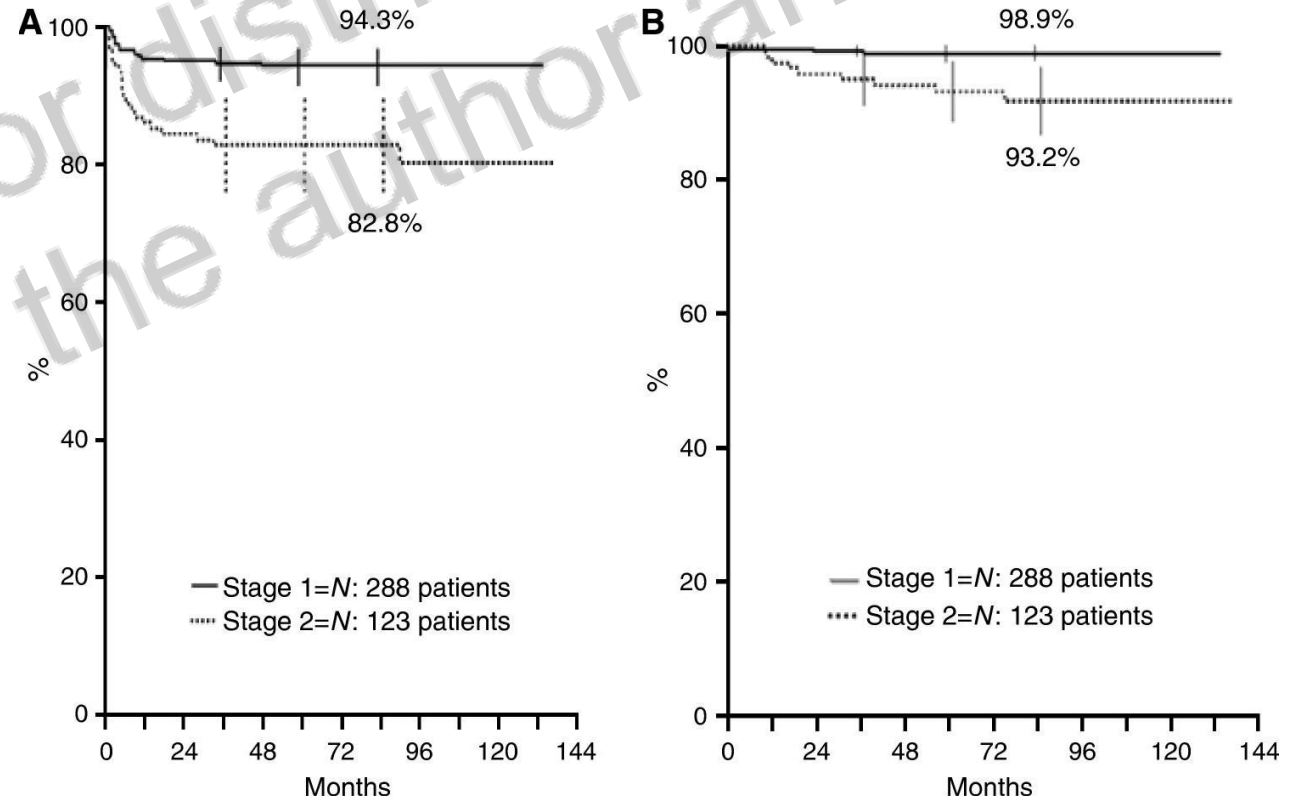

# Background for Siopen Low & Intermediate Risk Strategy

## ■ LNESG1 Study

(Di Bernardi & J. Michon et al, Br J Cancer. 2008 Oct 7; 99(7): 1027–1033.

### Conclusion:

- Surgery alone was effective and safe treatment for localised resectable neuroblastoma yielded by excellent OS for both stage 1 and 2 neuroblastoma without MYCNA,
- Stage 2 patients with unfavourable histopathology and elevated LDH suffered a high number of relapses.
- Both stage 1 and 2 patients with amplified MYCN gene (MYCNA) were at greater risk of relapse.

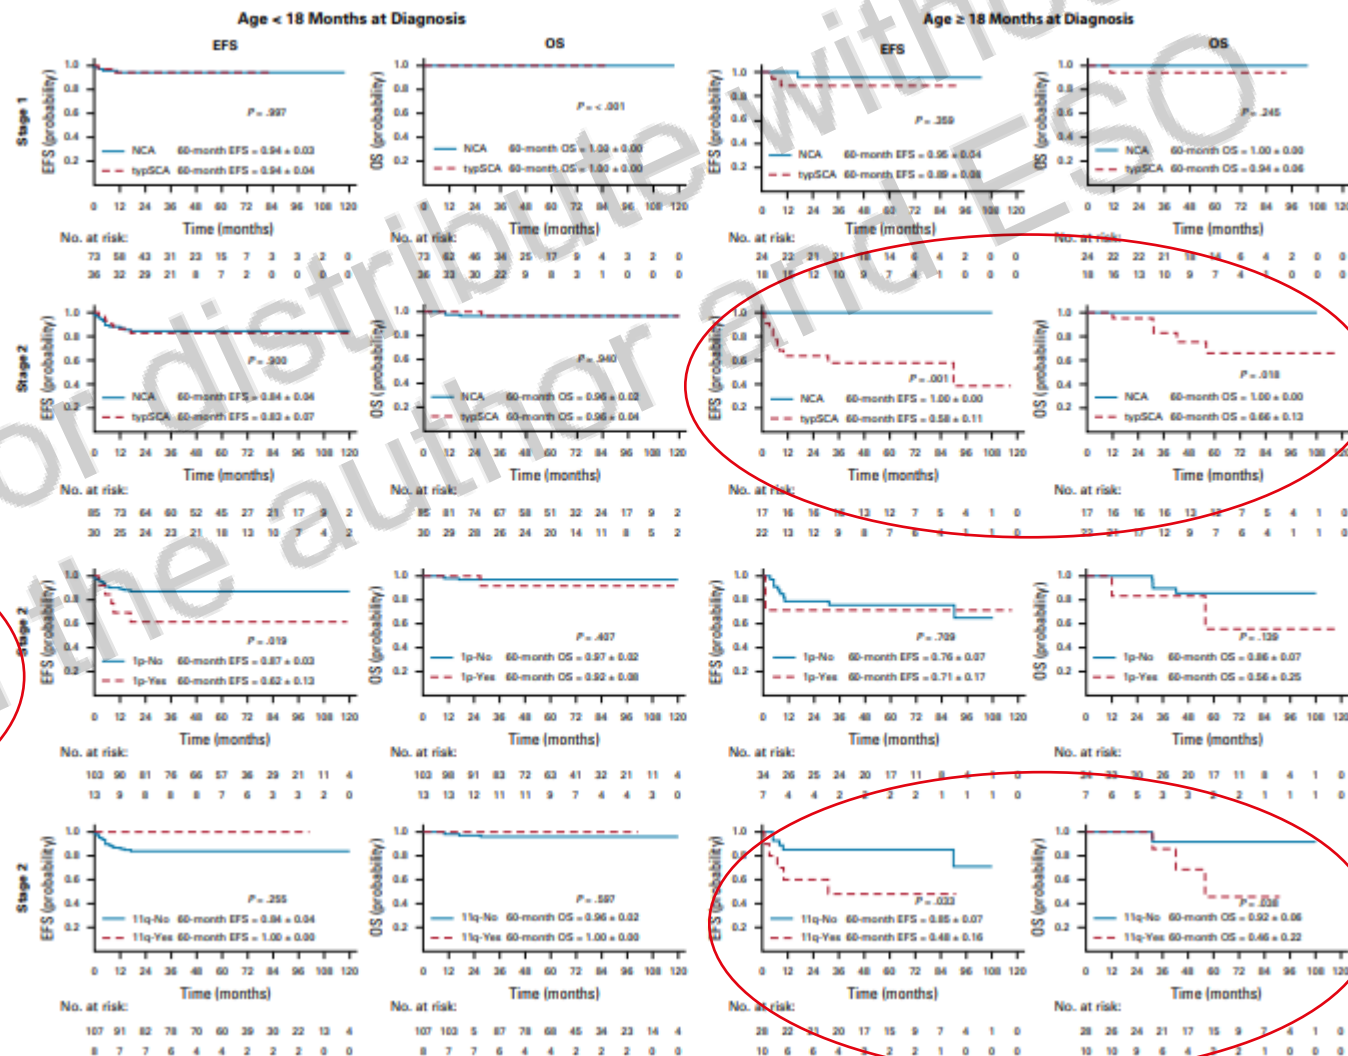

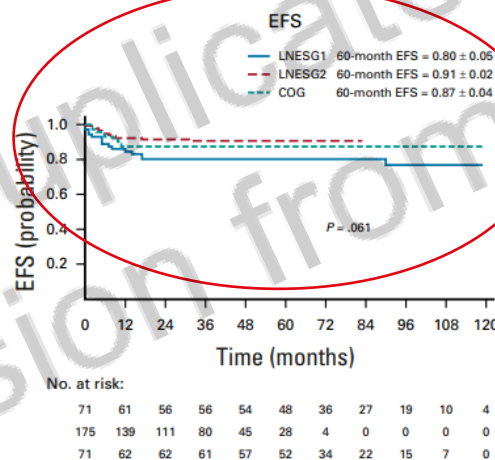

# Background for Siopen Low & Intermediate Risk Strategy

- Age Dependency of the Prognostic Impact of Tumor Genomics in Localized Resectable MYCN-Nonamplified Neuroblastomas. Report From the SIOPEL Biology Group on the LNESG Trials and a COG Validation Group

Ambros et al, J Clin Oncol 2020; 38:3685-3697

## Conclusions:

- Genomic analyses of localized, resectable neuroblastomas from 2 consecutive European studies and a North American cohort revealed a different prognostic impact of tumor genomics depending on patient age (< or ≥ 18 months).
- The presence of segmental chromosome aberrations, especially 11q loss, significantly reduced survival in patients ≥ 18 months of age with stage 2 neuroblastoma, but not in the cohort < 18 months.

# The International Neuroblastoma Risk Group (INRG) Staging System: An INRG Task Force Report

Tom Monclair, Garrett M. Brodeur, Peter F. Ambros, Hervé J. Brisse, Giovanni Cecchetto, Keith Holmes, Michio Kaneko, Wendy B. London, Katherine K. Matthay, Jed G. Nuchtern, Dietrich von Schweinitz, Thorsten Simon, Susan L. Cohn, and Andrew D.J. Pearson

**Table 2.** International Neuroblastoma Risk Group Staging System

Stage	Description
L1	Localized tumor not involving vital structures as defined by the list of image-defined risk factors and confined to one body compartment
L2	Locoregional tumor with presence of one or more image-defined risk factors
M	Distant metastatic disease (except stage MS)
MS	Metastatic disease in children younger than 18 months with metastases confined to skin, liver, and/or bone marrow

NOTE. See text for detailed criteria. Patients with multifocal primary tumors should be staged according to the greatest extent of disease as defined in the table.

BM studies

■ SIOPEN considerations for treatment strategy:

- Age cut-off 12 months for M and MS .
- All infants with M or Ms metastases are low risk except those with bony metastases demonstrated by CT, lung/pleura or CNS metastases (Intermediate risk).

# The International Neuroblastoma Risk Group (INRG) Staging System: An INRG Task Force Report

Tom Monclair, Garrett M. Brodeur, Peter F. Ambros, Hervé J. Brisse, Giovanni Cecchetto, Keith Holmes, Michio Kaneko, Wendy B. London, Katherine K. Matthay, Jed G. Nuchtern, Dietrich von Schweinitz, Thorsten Simon, Susan L. Cohn, and Andrew D.J. Pearson

[J Clin Oncol.](#) 2009 Jan 10; 27(2):

INRG Stage	Age (months)	Histologic Category	Grade of Tumor Differentiation	MYCN	11q Aberration	Ploidy	Pretreatment Risk Group
L1/L2		GN maturing; GNB intermixed					A Very low
L1		Any, except GN maturing or GNB intermixed		NA			B Very low
				Amp			K High
L2	< 18	Any, except GN maturing or GNB intermixed		NA	No		D Low
					Yes		G Intermediate
			Differentiating	NA	No		E Low
	≥ 18	GNB nodular; neuroblastoma			Yes		H Intermediate
			Poorly differentiated or undifferentiated	NA			
				Amp			N High
M	< 18			NA		Hyperdiploid	F Low
	< 12			NA		Diploid	I Intermediate
	12 to < 18			NA		Diploid	J Intermediate
	< 18			Amp			O High
	≥ 18						P High
MS					No		C Very low
	< 18			NA	Yes		Q High
				Amp			R High

## Siopen Low Risk Group

Children with

- L1 Neuroblastoma, without Nmyc amplification.
- Children < 18 months with L2 neuroblastoma without MycN amplification.
- Infants (0-12 months) with M\*/Ms\* Neuroblastoma without MycN amplification.
- Neonatal adrenal masses MIBG positive.

# Siopen Intermediate Risk Group

Children with

- Stage **INRG L2 > 18 months**, i.e. localised neuroblastoma without MycN amplification associated with image defined risk factors (IDRFs)
- **Stage INRG M  $\leq$  12 months** with disseminated neuroblastoma involving bone, pleura, lungs and/or CNS without MycN amplification
- 
- **Localised resected NBL ( stage INSS 1) with MYCN amplification**

Treatment recommendations are based on  
algorithm combining:  
age-stage-genomic profile-LTS

# Siopen Life Threatening Symptoms:

The presence of any of these symptoms is an indication for chemotherapy.

## Intraspinal neuroblastoma(See Appendix 13, page 182)

Patients who either have symptoms of spinal cord involvement or have a spinal tumour component that occupies more than one third of the spinal canal on the axial plane and/or the perimedullary leptomeningeal spaces are not visible and/or the spinal cord signal is abnormal.

## Systemic upset

- Pain requiring opiate treatment
- Gastrointestinal
  - Vomiting needing nasogastric/IV support
  - Weight loss >10%body weight

*NOTE: diarrhoea with VIP does not respond to chemotherapy and is a definite indication for surgery*
- Respiratory
  - Respiratory distress without evidence of infection
    - Tachypnoea >60
    - Oxygen need
    - Ventilatory support
- Cardiovascular System
  - Hypertension
  - IVC involvement +/- leg oedema
- Renal
  - Impaired renal function, creatinine increased x 2 ULN<sup>1</sup>
  - Poor urine output, less than 2mls/kg/hour
  - Hydroureter/hydronephrosis
- Hepatic
  - Abnormal liver function >2 ULN
  - Evidence of DIC
  - Platelets <50 x 10<sup>9</sup>/l
- Bladder/Bowel dysfunction secondary to a mass effect.

A very larger tumour volume causing concern of possible tumour rupture and/or the possible rapid development of systemic upset.

# Spinal Cord Compression (SCC)

- In neuroblastoma patients high expectation at diagnosis and during treatment
- Considered a **Life threatening symptom (LTS)** in LINES and for the low-risk NB guideline in both symptomatic and asymptomatic patients: recommendation to start urgent chemo (Vp/Carbo)
  - Symptomatic pts: pain and potentially irreversible loss of neurologic function)
  - Asymptomatic pts: concept of spinal cord involvement
- **Symptomatic patients are an emergency (urgent neurosurgery vs chemotherapy + high dose of glucocorticoids)**  
Discussion with Neurosurgery team!!
- SCC SIOPEN study

# Opsoclonus Myoclonus Syndrome (OMS)

- Almost 50% of children with OMS have an underlying NB, but OMS precedes NB in 50% of cases
- Approx. 2% of children with NB develop paraneoplastic OMS, rather associated with favorable NBL
- Paraneoplastic syndrome (and non-paraneoplastic):
  - rare 0.18 cases per million per year\*
  - mean age 1.5 to 2 years
- Importance of initiate as soon as possible specific treatment (independent of NB's trt; glucocorticoids as first step \*OMS/DES 2008 CT).
- Prognosis different from NB disease (independent and usually worse, residual symptoms)

# High-Risk Neuroblastoma

- Prognostic Features COG:
  - Age > 18 months,
  - Advanced stage disease,
  - Tumor MYCN amplification,
  - Poorly or undifferentiated tumor
  - Tumor diploid DNA content
  
- Prognostic Features SIOPEN / HR-NBL1:
  - Age > 12 months,
  - Tumor MYCN amplification in INSS stage  $\geq 2$
  - Metastatic disease > 12 months
  - Stage 4s with MycN Amplification

# Building the evidence - Randomised trials in High-Risk neuroblastoma

permission from the author and ESO

# ENSG-1(UK) : High dose melphalan in the treatment of advanced neuroblastoma: results of a randomised trial

*Pritchard, Pediatric Blood & Cancer, 44, 2005*

## BACKGROUND

Addition of melphalan HDC in a randomised, multi-centre trial 1982 to 1985 including 167 children with stages IV and III neuroblastoma (123 stage IV > 1 year old at diagnosis and 44 stage III and stage IV from 6 to 12 months old at diagnosis) after induction with OPEC every 3 weeks, surgical excision of primary tumour: 90 patients (69% of the total) achieving CR or GPR )were randomised to either HD melphalan (180 mg/m<sup>2</sup>) with autologous BMT or to no further treatment.

## RESULTS

72% of eligible children were randomised with 21 surviving with a FU from randomisation of 14.3 years. 5-yr EFS was 38% in the HDC melphalan group and 27% in the "no-melphalan" group. This difference was not statistically significant (P = 0.08, log rank test) but for the **48 randomised stage IV patients aged >1 year at diagnosis outcome was significantly better in the melphalan-treated group-5 year EFS 33% versus 17% (P = 0.01, log rank test).**

## CONCLUSIONS

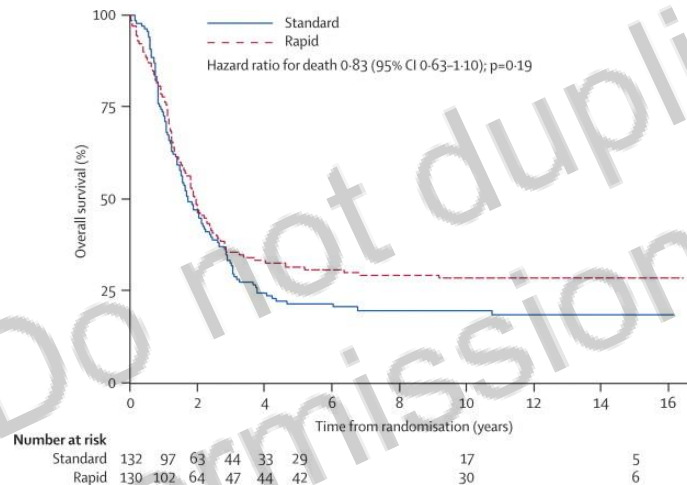

HD - melphalan improved EFS and OS who achieved CR or GPR after OPEC induction and surgery.

# COG: LTFU of CCG-3891 HR-Neuroblastoma treated on a Randomized Trial of Myeloablative Therapy Followed by 13-cis-RA.

Matthay, Journal of Clinical Oncology, 2009

**METHODS:** Random assignment to HDC +TBI / purged bone marrow transplantation (ABMT) or 3 intense chemotherapy cycle and subsequent 13 cis-RA)

**RESULTS:** 5-yr EFS was significantly higher for HDC/ABMT than chemotherapy with  $30\% \pm 4\%$  versus  $19\% \pm 3\%$ , respectively ( $P = .04$ ). The 5-year EFS ( $42\% \pm 5\%$  v  $31\% \pm 5\%$ ) from the time of second random assignment was higher for cis-RA than for no further therapy, though it was not significant.

The 5-yr OS from the second random assignment of patients who underwent both random assignments and who were assigned to ABMT/cis-RA was  $59\% \pm 8\%$ ; for ABMT/no cis-RA, it was  $41\% \pm 7\%$ ; for continuing chemotherapy/cis-RA, it was  $38\% \pm 7\%$ ; and for chemotherapy/no cis-RA, it was  $36\% \pm 7\%$ .

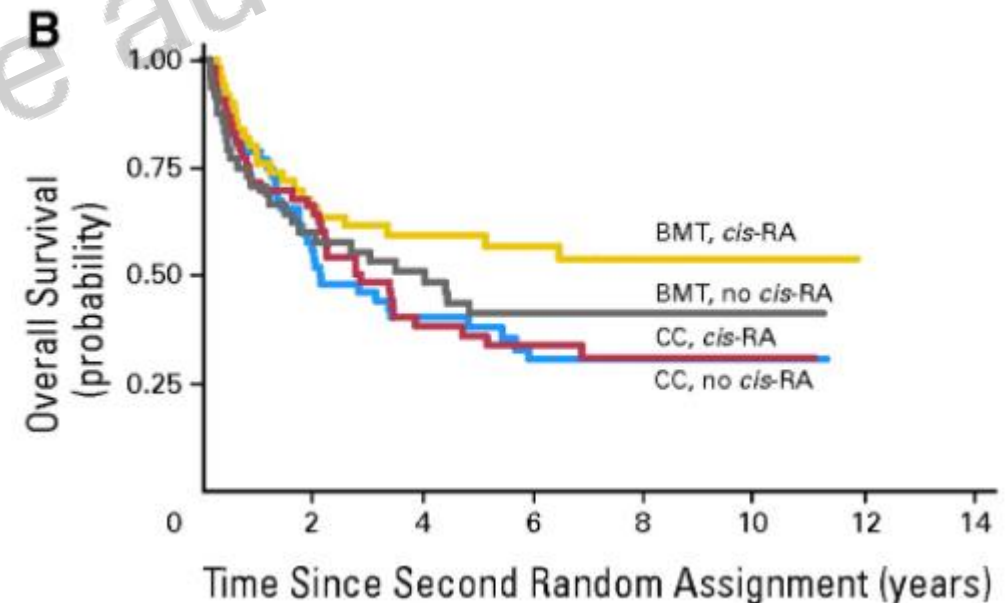

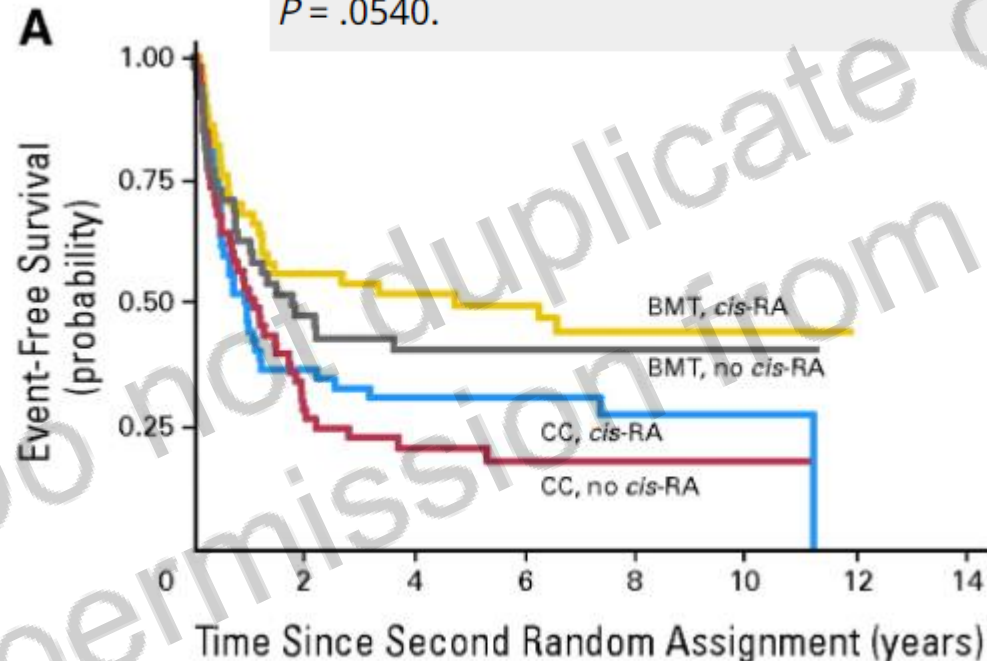

## CONCLUSION

HDC/TBI /ABMT resulted in significantly better 5-yr EFS than intense chemotherapy; however, neither myeloablative therapy with autologous hematopoietic cell rescue nor cis-RA given after consolidation therapy significantly improved OS.

# COG: LTFU of CCG-3891 HR-Neuroblastoma treated on a Randomized Trial of Myeloablative Therapy Followed by 13-cis-RA. *Matthay, Journal of Clinical Oncology, 2009*

(A) Event-free survival for patients who participated in both the first and second random assignments (autologous bone marrow transplantation + 13-*cis*-retinoic acid [*cis*-RA] [n = 50] versus continuing chemotherapy (CC) + no *cis*-RA [n = 53]).  $P = .0038$ .  
(B) Overall survival for patients who participated in both the first and second random assignments (autologous bone marrow transportation + *cis*-RA versus CC + no *cis*-RA)  $P = .0540$ .

# GPOH: LTFU of the GPOH NB97 trial for high-risk neuroblastoma comparing HDCT/SCT and oral chemotherapy as consolidation

*F. Berthold, British Journal of Cancer, 2018*

## **METHODs:**

A randomised open label trial 1997–2004 (Germany, Switzerland) with 295 patients with HR-NBL randomly assigned to HDC (MEC) /ASCT or maintenance chemotherapy (MT) for consolidation. Analyses were done by intention-to-treat (ITT: ASCT/MT N = 149/146), as treated (AT: N = 110/102), and treated as randomised (TAR: N = 75/70).

**RESULTS** The EFS superior with ASCT compared to MT in all three cohorts (hazard ratio [HR] for ITT 1.39, 95% confidence interval (CI) 1.05-1.85,  $P = 0.022$ , HR for AT 1.75, CI 1.24-2.47,  $P = 0.001$ ; HR for TAR 2.07, CI 1.36-3.16,  $P = 0.001$ ).

OS also in favour of the ASCT groups (ITT:  $P = 0.075$ ; AT:  $P = 0.017$ ; TAR:  $P = 0.005$ ). The frequencies of late sequelae were not different except for focal nodular hyperplasia of the liver observed more frequently in the ASCT arm

## **CONCLUSIONS**

HDC /ASCT had a better long-term outcome compared to maintenance CHT.

# COG A3973: Purged versus non-purged PBSCT for HR-NBL

*Kreissman, Lancet Oncol, 14; 2013*

## BACKGROUND

Randomised study of tumour-selective PBSC purging in SCT HR-NBL pts between 2001 -2006 to receive either non-purged or immunomagnetically purged PBSC. ( Strata on INSS &INPC, age, MYCN status)  
6 cycles of induction CHT, HDC /SCT, and radiation therapy to the primary tumour site plus mIBG treatment to avoid metastases present prior HDC followed by oral isotretinoin. PBSC collection was done after two induction cycles.

## RESULTS

486 randomly assigned , of whom 243 patients to receive non-purged PBSC. 5-year EFS 40% (95% CI 33–46) in the purged group versus 36% (30–42) in the non-purged group ( $p=0.77$ ); 5-year OS was 50% (95% CI 43–56) in the purged group compared with 51% (44–57) in the non-purged group ( $p=0.81$ ).

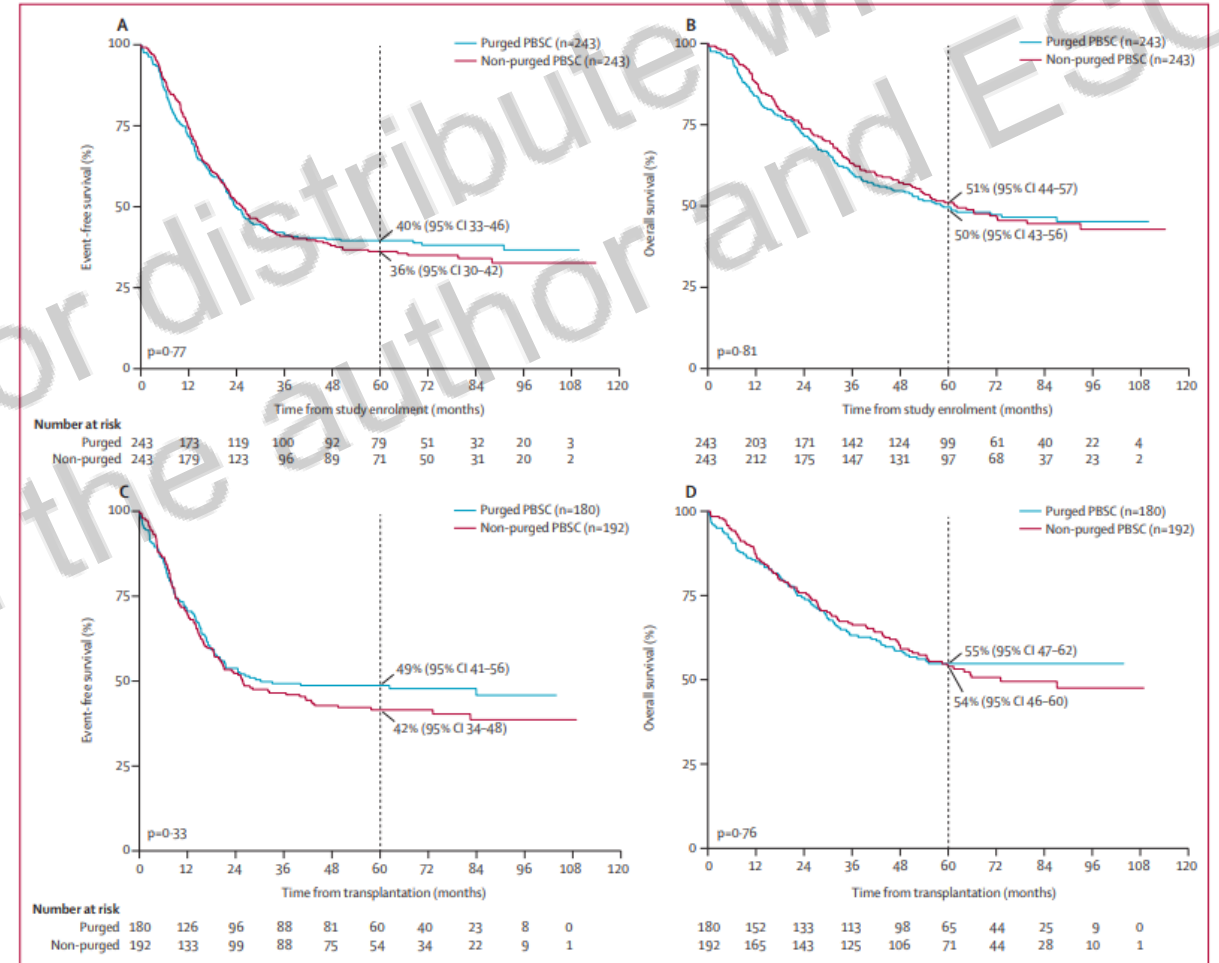

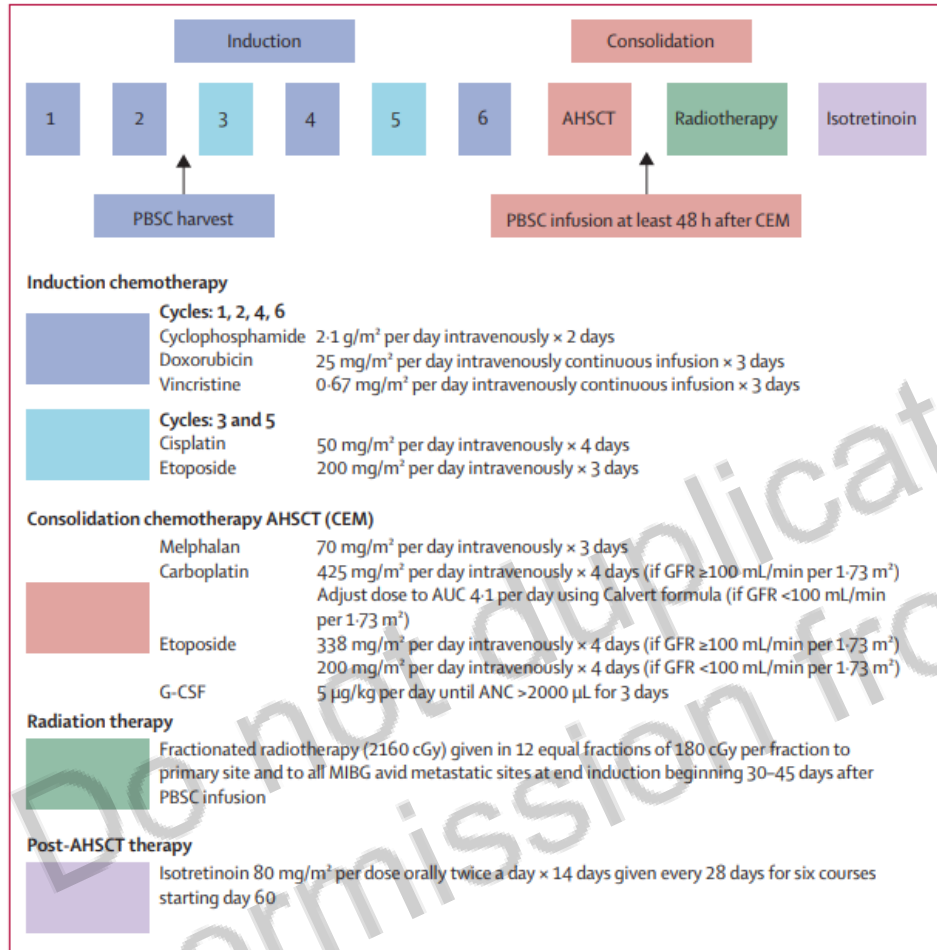

## INTERPRETATION

Immunomagnetic purging of PBSC for autologous stem-cell transplantation did not improve outcome, perhaps because of incomplete purging or residual tumour in patients. Non-purged PBSC are acceptable for support of myeloablative therapy of high-risk neuroblastoma.

# COG A3973: Purged versus non-purged PBSCT for HR-NBL

*Kreissman, Lancet Oncol, 14; 2013*

# COG: ANBL0532 Effect of Tandem ASCT vs Single SCT on EFS in HR- Neuroblastoma

*Park et al, JAMA, 2019 Aug 27;322(8):746-755.*

**METHODS:** 652 eligible patients enrolled (2007 – 2012) at 142 COG centers (US, Canada, Switzerland, Australia, and New Zealand) with protocol-defined high-risk neuroblastoma with 355 randomized to either Tandem SCT (thiotepa/cyclophosphamide followed by dose-reduced carboplatin/etoposide/melphalan (n = 176) or single SCT with carboplatin/etoposide/melphalan (n = 179).

**RESULTS:** In 355 patients randomized, 297 patients (83.7%) completed the study. 3 year EFS from the time of randomization was 61.6% (95% CI, 54.3%-68.9%) in the tandem transplant group and 48.4% (95% CI, 41.0%-55.7%) in the single transplant group (1-sided log-rank P=.006). FU was 5.6 (0.6-8.9) years. The most common significant toxicities following tandem vs single transplant were mucosal (11.7% vs 15.4%) and infectious (17.9% vs 18.3%).

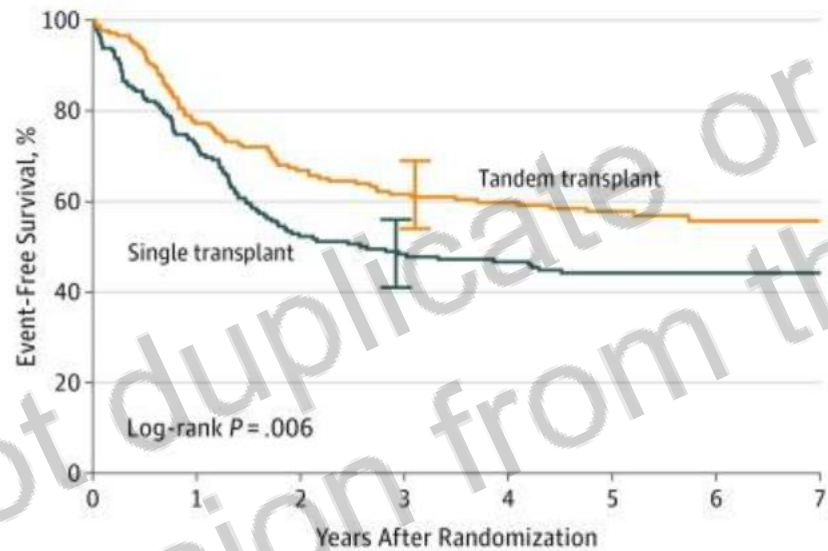

## **CONCLUSIONS:**

Tandem transplant resulted in a significantly better EFS than single transplant. However, because of the low randomization rate, the findings may not be representative of all patients with high-risk neuroblastoma.

### Starting infusion durations:

- GPOH: starting dinutuximab beta infusion duration = 5 days  $10 \text{ mg/m}^2 \times 5 \text{ days}$  ( $50 \text{ mg/m}^2/\text{course}$ ) at 21-day treatment intervals.
- COJEC: starting dinutuximab beta infusion duration = 3 days  $10 \text{ mg/m}^2 \times 3 \text{ days}$  ( $30 \text{ mg/m}^2/\text{course}$ ) at 10-day treatment intervals.

**COJEC = cisplatin, vincristine, carboplatin, etoposide, and cyclophosphamide; GPOH = German Pediatric Oncology and Hematology; HDC BuMel = high-dose chemotherapy busulfan and melphalan; PBSC = peripheral blood stem cells.**

# Critical appraisal and Conclusions 1

- Neuroblastoma is marked by wide clinical and biological heterogeneity rendering comparisons across respective trials with varying eligibility and treatment intensities per se difficult.
- Over the past 4 decades, outcomes for children with high-risk neuroblastoma have improved by better identification of high-risk groups
- Therapy de-escalation in the low- intermediate risk group as important element for children with favourable biological profiles and no LTS.
- Therapy intensification was beneficial in high risk neuroblastoma with one of the most significant improvements achieved by introduction of HDC/autologous SCT.
- Hallmark randomized trials addressing HDC/SCT underpinned results of earlier single arm HDC /SCT trials in NBL overcoming poor long term outcome results of previously 10 to 20% OS.

## Critical appraisal and Conclusions 2

- However, unless we achieve long term survival rates in HR-NBL comparable to ALL with > 90% de-escalation strategies appear not advisable and rather synergistic approach of available treatment modalities including innovative ones should be further explored and new evidence be created.
- Continued collaborative efforts are necessary with a respectful, albeit critical appraisal of new insights to built together optimized treatment concepts and to create new evidence for children with high risk neuroblastoma to achieve our common vision:  
A long term survival for all our patients with reduced toxicity and minimal late effects!

Thank you!
